Reference Hardened RKE <code>cluster.yml</code> Configuration	7
Reference Hardened RKE Template configuration	15
Reference Hardened cloud-config	19

This document provides prescriptive guidance for hardening a production installation of a RKE cluster to be used with Rancher v2.6.3. It outlines the configurations and controls required to address Kubernetes benchmark controls from the Center for Information Security (CIS).

This hardening guide describes how to secure the nodes in your cluster, and it is recommended to follow this guide before installing Kubernetes.

This hardening guide is intended to be used for RKE clusters and associated with specific versions of the CIS Kubernetes Benchmark, Kubernetes, and Rancher:

Rancher Version	CIS Benchmark Version	Kubernetes Version
Rancher v2.6.3	Benchmark v1.6	Kubernetes v1.18, v1.19, v1.20 and v1.21

[Click here to download a PDF version of this document.](#)

## Overview

This document provides prescriptive guidance for hardening a RKE cluster to be used for installing Rancher v2.6.3 with Kubernetes v1.18 up to v1.21 or provisioning a RKE cluster with Kubernetes v1.18 up to v1.21 to be used within Rancher v2.6.3. It outlines the configurations required to address Kubernetes benchmark controls from the Center for Information Security (CIS).

For more detail about evaluating a hardened cluster against the official CIS benchmark, refer to the [CIS 1.6 Benchmark – Self-Assessment Guide – Rancher v2.6](#).

## Known Issues

- Rancher exec shell and view logs for pods are not functional in a CIS v1.6 hardened setup when only public IP is provided when registering custom nodes. This functionality requires a private IP to be provided when registering the custom nodes.
- When setting the `default_pod_security_policy_template_id:` to `restricted`, Rancher creates RoleBindings and

ClusterRoleBindings on the default service accounts. The CIS v1.6 check 5.1.5 requires that the default service accounts have no roles or cluster roles bound to it apart from the defaults. In addition the default service accounts should be configured such that it does not provide a service account token and does not have any explicit rights assignments.

## Configure Kernel Runtime Parameters

The following `sysctl` configuration is recommended for all nodes type in the cluster. Set the following parameters in `/etc/sysctl.d/90-kubelet.conf`:

```
vm.overcommit_memory=1
vm.panic_on_oom=0
kernel.panic=10
kernel.panic_on_oops=1
kernel.keys.root_maxbytes=25000000
```

Run `sysctl -p /etc/sysctl.d/90-kubelet.conf` to enable the settings.

## Configure `etcd` user and group

A user account and group for the `etcd` service is required to be setup before installing RKE. The uid and gid for the `etcd` user will be used in the RKE `config.yml` to set the proper permissions for files and directories during installation time.

### Create `etcd` user and group

To create the `etcd` group run the following console commands.

The commands below use `52034` for uid and gid are for example purposes. Any valid unused uid or gid could also be used in lieu of `52034`.

```
groupadd --gid 52034 etcd
useradd --comment "etcd service account" --uid 52034 --gid 52034 etcd --shell /usr/sbin/nologin
```

Update the RKE `config.yml` with the uid and gid of the `etcd` user:

```
services:
  etcd:
    gid: 52034
    uid: 52034
```

## Set `automountServiceAccountToken` to `false` for `default` service accounts

Kubernetes provides a default service account which is used by cluster workloads where no specific service account is assigned to the pod. Where access to the Kubernetes API from a pod is required, a specific service account should be created for that pod, and rights granted to that service account. The default service account should be configured such that it does not provide a service account token and does not have any explicit rights assignments.

For each namespace including default and kube-system on a standard RKE install, the default service account must include this value:

```
automountServiceAccountToken: false
```

Save the following configuration to a file called `account_update.yaml`

```
apiVersion: v1
kind: ServiceAccount
metadata:
  name: default
automountServiceAccountToken: false
```

Create a bash script file called `account_update.sh`. Be sure to `chmod +x account_update.sh` so the script has execute permissions.

```
#!/bin/bash -e

for namespace in $(kubectl get namespaces -A -o json | jq -r '
.items[].metadata.name'); do
  kubectl patch serviceaccount default -n ${namespace} -p "$(cat
account_update.yaml)"
done
```

## Ensure that all Namespaces have Network Policies defined

Running different applications on the same Kubernetes cluster creates a risk of one compromised application attacking a neighboring application. Network segmentation is important to ensure that containers can communicate only with those they are supposed to. A network policy is a specification of how selections of pods are allowed to communicate with each other and other network endpoints.

Network Policies are namespace scoped. When a network policy is introduced to a given namespace, all traffic not allowed by the policy is denied. However, if there are no network policies in a namespace all traffic will be allowed into and out of the pods in that namespace. To enforce network policies, a CNI (container network interface) plugin must be enabled. This guide uses [Canal](#) to provide the policy enforcement. Additional information about CNI providers can be found [here](#).

Once a CNI provider is enabled on a cluster a default network policy can be applied. For reference purposes a permissive example is provided below. If you want to allow all traffic to all pods in a namespace (even if policies are added that cause some pods to be treated as “isolated”), you can create a policy that explicitly allows all traffic in that namespace. Save the following configuration as [default-allow-all.yaml](#). Additional [documentation](#) about network policies can be found on the Kubernetes site.

This `NetworkPolicy` is just an example and is not recommended for production use.

```
---
apiVersion: networking.k8s.io/v1
kind: NetworkPolicy
metadata:
  name: default-allow-all
spec:
  podSelector: {}
  ingress:
  - {}
  egress:
  - {}
  policyTypes:
```

- Ingress
- Egress

Create a bash script file called `apply_networkPolicy_to_all_ns.sh`. Be sure to `chmod +x apply_networkPolicy_to_all_ns.sh` so the script has execute permissions.

```
#!/bin/bash -e

for namespace in $(kubectl get namespaces -A -o json | jq -r '
.items[].metadata.name'); do
    kubectl apply -f default-allow-all.yaml -n ${namespace}
done
```

Execute this script to apply the `default-allow-all.yaml` configuration with the permissive `NetworkPolicy` to all namespaces.

## Reference Hardened RKE `cluster.yml` Configuration

The reference `cluster.yml` is used by the RKE CLI that provides the configuration needed to achieve a hardened install of Rancher Kubernetes Engine (RKE). RKE install [documentation](#) is provided with additional details about the configuration items. This reference `cluster.yml` does not include the required nodes directive which will vary depending on your environment. Documentation for node configuration in RKE can be found [here](#).

For a Kubernetes v1.28 cluster, the configuration `spec.volumes: 'ephemeral'` should be removed from the `PodSecurityPolicy`, since it's not supported in this Kubernetes release.

```
# If you intend to deploy Kubernetes in an air-gapped
environment,
# please consult the documentation on how to configure custom
RKE images.
# https://rancher.com/docs/rke/latest/en/installation/ .
```

```
# The nodes directive is required and will vary depending on
your environment.
# Documentation for node configuration can be found here:
# https://rancher.com/docs/rke/latest/en/config-options/nodes/

## Reference Hardened cloud-config

The reference cloud-config is generally used in cloud infrastructure environments to allow for configuration management of compute instances. The reference config configures SUSE Linux Enterprise Server (SLES) and Ubuntu operating system level settings needed before installing Kubernetes.

### Reference Hardened cloud-config for SUSE Linux Enterprise Server 15 (SLES 15)

```

#cloud-config
system_info:
  default_user:
    groups:
      - docker
write_files:
  - path: "/etc/sysctl.d/90-kubelet.conf"
    owner: root:root
    permissions: '0644'
    content: |
      vm.overcommit_memory=1

```

```

    vm.panic_on_oom=0
    kernel.panic=10
    kernel.panic_on_oops=1
    kernel.keys.root_maxbytes=25000000
package_update: true
runcmd:
# Docker should already be installed in SLES 15 SP3
- zypper install docker containerd
- systemctl daemon-reload
- systemctl enable docker.service
- systemctl start --no-block docker.service
- sysctl -p /etc/sysctl.d/90-kubelet.conf
- groupadd --gid 52034 etcd
- useradd --comment "etcd service account" --uid 52034 --gid
52034 etcd --shell /usr/sbin/nologin

```

## Reference Hardened cloud-config for Ubuntu 20.04 LTS

```

#cloud-config
system_info:
  default_user:
    groups:
      - docker
write_files:
- path: "/etc/sysctl.d/90-kubelet.conf"
  owner: root:root
  permissions: '0644'
  content: |
    vm.overcommit_memory=1
    vm.panic_on_oom=0
    kernel.panic=10
    kernel.panic_on_oops=1
    kernel.keys.root_maxbytes=25000000
package_update: true
runcmd:
# Install Docker from Rancher's Docker installation scripts -
github.com/rancher/install-docker

```

```
- curl https://releases.rancher.com/install-docker/20.10.sh |  
sh  
- systemctl -p /etc/systemd.d/90-kubelet.conf  
- groupadd --gid 52034 etcd  
- useradd --comment "etcd service account" --uid 52034 --gid  
52034 etcd --shell /usr/sbin/nologin
```
